## ACKNOWLEDGEMENT

The matching procedure resulted in the comparable groups having a particular composition, and findings with regard to these groups thus cannot be generally applied to the population at large.

The conclusion that can be drawn from this investigation (and from various others, e.g. Himmelweit, Oppenheim and Vince 1958; Schramm, Lyle and Parker 1961; Furu 1962 and De Beer 1980) is that television probably has the potential to affect children's interests. It was found in this investigation that the test group's interest had been stimulated in social work and law while it had declined in the performing arts , and historical matters. The contents of certain television programmes probably contributed to a change in children's interests (cf. De Beer, 1980). It is recommended that further research be conducted on the qualilative and quantitative contents of the television programmes transmitted in the RSA to shed more light on the effect of television on children's interests.

The information contained in this research finding was obtained from Project COMM 11 that was conducted to determine the effect of television on schoolchildren. Data were collected in schools in all four provinces of the RSA.

Thanks are due to the following persons and bodies for their contribution to the planning and implementation of the project.

The Committee of Heads of Education who gave permission for the project to be undertaken;
the principals of schools and their staff who served as testers;
the school psychologists of the Psychological and Guidance Service of the different education departments who were respon= sible for the training of the testers;
the pupils who served as respondents; and
members of the ad hoc committee who helped with the planning of the project, namely:

with greater caution than in Fields 3 and 14 where statistically significant differences were found with regard to both matched groups.

SUMMARY AND CONCLUSION

The aim of the investigation was to study the effect of television on the interest patterns of Standard Nine pupils. The sample was divided into two pre= television groups (the pupils tested respectively in 1974 and 1975) and a television viewer group (1977). The latter was divided into a heavy viewer group (respondents who watched television for an hour or longer a day during school terms) and a light viewer group (pupils who watched television for less than an hour a day during school terms). Other conditions for inclusion were that television viewers should have had a television set at home for at least three months and that they were not to have watched television el sewhere.

To ensure comparability between the groups of pre= television viewers, heavy viewers and light viewers, a process of matching was applied with regard to six extraneous variables that were identified through a stepwise regression analys.is. The six extraneous variables that explained most of the variation in the test group's interests are sex, home language, the pupil's occupational choice, course followed at school and whether the pupil took a third language and Geography.
pretelevision group (Tables 3 and 4 as well as 6 and 7).
CONTENTS
4.3.2 Historical (Field 7)

For the 1974/1977 matched groups a statistically significant difference was found between the means of the experimental and the control difference scores in the field of historical interests ( $p<0,05$; Table 5). This field is concerned with pupils' interest in visits to battlefields and museums, old forts and churches, the reading of historical literature and the collecting of antiques. As in the case of the previous field, the mean scores of the heavy viewers for this field were statistically significantly lower than those of the pretelevision group while the mean scores of the light viewers did not differ significantly from those of the pretelevision group (as can be seen from an inspection of Tables 3 and 4 as well as 6 and 7).

Television probably caused a decrease: in the interest of the Standard Nine pupils in the matched groups in the performing arts and historical matters, which Alberts (1974) grouped together under the heading Aesthetic interests.

In Fields 5 and 7 where a statistically significant difference between the means of the experimental and the control difference scores occured only with regard to one matched group, the interpretation that television can be responsible for this difference should be made

4.2.2 Law (Field 14)

The calculations of the $t$ tests in both the 1974/4977 and the 1975/1977 matched groups (Tables 5 and 8) showed statistically significant differences between the mean of the experimental difference scores and the control difference scores (1974/1977: p < 0,01 and 1975/1977: p < 0,05). This indicates that television probably stimulated these pupils' interest in law. In both matched groups the 19 FII scores of the heavy viewers were higher than those of the light viewers (according to inspection of Tables 3 and 4 as well as 6 and 7). De Beer (1980) found a similar stimulating effect of television on the interests of Standard Ten pupils in law.
4.3 FIELDS IN WHICH THE INTEREST CHANGED (DECREASED)
4.3.1 Performing Arts (Field 5)

This field is concerned with interest in music, singing, ballet, opera and operetta. A statistically signifi= cant difference was found here in the 1975/1977 matched groups ( $p<0,05$ ), which indicates that television probably caused a decrease in the experimental groups '. interest in the performing arts. Statistically the heavy viewers' mean scores for this field was signi= ficantly lower than that of the pretelevision group while the light viewers' mean scores showed no statis= tically significant difference from those of the

## INTRODUCTION

The data contained in this research finding form part of a comprehensive project that is being undertaken by the South African Institute for Communication Research of the HSRC to study the effect of television on schoolchildren. The investigation resulted from the recommendations of the Commission of Inquiry into Matters relating to Television and of the Technical Advisory Committee of the SABC, namely that research be conducted on the sociocultural structure of South African society and the effect television may have on it.

The investigation is being conducted among pupils in Standard Three to Standard Ten in provincial schools in the Transvaal, Natal, the Cape and the Orange Free State.

Data.for the project are collected through questionnaires and standardized tests and the personalities, attitudes (persona1, home, social and formal), value orientations, social behaviour, study habits and attitudes, time utilization and interests of pupils are studied. Because of the extent of the data that have already been collected on each of these factors, in this investigation attention will be devoted only to the interest patterns of Standard Nine pupils*.
*Standard Nine is the second last year of high school.

In overseas research little attention has been devoted to the effect of television on children's interests. Indications have however been found that television has the potential to affect children's interests. Schramm, Lyle and Parker (1961) found in the USA that television can probably stimulate children's interests but that it does not really encourage them towards new activities or creativity. Similar findings were obtained in Japan (Furu, 1962) and in England (Himmelweit, Oppenheim and Vince, 1958).

De Beer (1980) also found in the RSA that television pro= bably has the potential to affect children's interests. In a study of Standard Ten pupils he found that television probably stimulated these pupils' interests in law and homecrafts while it weakened their interests in social work. These groups however consisted mainly of Afrikaansspeaking girls, with the result that the findings are not applicable to the general population of Standard Ten pupils.

The aim of the investigation is to determine whether television has an effect on the interest patterns of Standard Nine pupils.

3 METHOD
3.1 MEASURING INSTRUMENTS

For the purpose of this investigation use was made of data collected with the 19 Field Interest Inventory, the Biographical Questionnaire and the Television Questionnaire.
3.1.1 The 19 Field Interest Inventory (19 FII)

The 19 FII is a standardized questionnaire of the HSRC used for measuring the interests of high school pupils (Standards 8; 9 and 10), students and adults (Fouché and Alberts, 1971). The questionnaire measures 19 broad fields of interest as well as the degree to which the respondent is actively or passively interested in the fields and whether his interests are job or hobby oriented.

The questionnaire measures interest orientation with regard to the following:

| Field | Measures interest in |
| :--- | :--- |
| 1 Fine arts | painting, sculpting, sketching, <br> advertisement design and <br> commercial art |
| 2 Clerical | stock control, typing, filing <br> and general administrative <br> office work |

-3-

| Field | Measures interest in |
| :--- | :--- |
| 3 Social Work | the rendering of service to <br> people in need of assistance <br> such as the blind, the deaf, <br> unmarried mothers, the aged <br> and underprivileged children |
| 4 Nature | activities pursued out of <br> doors such as agriculture, <br> animal husbandry and forestry |
| 5 Performing Arts | music, singing, ballet, opera <br> and operetta |
| 6 Science |  |
| *(natural science) | the physical and biological <br> sciences, e.g. chemical ana= <br> lysis, astronomy, bacteriology, |
| 7 Historical | nuclear physics and medicine |
| 8 visits to battlefields, museums, |  |
| forts and churches, reading |  |
| historical literature, collect= |  |
| ing antiques |  |

*Natural science is probably a more suitable name for this field.

-21-
for this field, which indicates that television probably 'stimulated these pupils' interest in social work (Tables 5 and 8 ). The mean 19 FII scores of the heavy viewers; for example, were consistently higher than those of the light viewers (according to inspection of Tables 3 and 4 as well as 6 and 7). An interesting point is that De Beer (1980) found that Standard Ten pupils' interest declined probably as a result of television. Possible explanations for these apparently contradictory findings may be that the compositions of the matched groups in the Standard Nine and Standard Ten investigations did not correspond closely enough, or that the interests of Standard Nine and Standard Ten pupils are not directly comparable. If one looks at the occupational choice development theory of Ginzberg et $\alpha$. (1951, as referred to by Van Vuuren, 1973) it appears that pupils between 15 and 16 years of age (value stage) are particularly oriented towards the idea of rendering service to the community. In the transitional stage however ( 17 to 18 years) adolescents are more oriented towards an immediate concrete decision on the choice of an occupation and towards reality. This orientation of the pupils could be the reason why Standard Nine pupils, more so than the Standard Ten pupils, were more interested in television programmes dealing with social work.

Inventory, Fouché and Alberts, 1971.)
3.1.2 Biographical questionnaire

The Biographical Questionnaire was designed by the South African Institute for Communication Research of the HSRC to obtain relevant biographical information on the respondents. The following questions were used.

1 What do you wish to become one day?
(If you have not decided, write: I do not know,)

Respondents' answers to the question were categorized as follows:

4 FINDINGS
4.1 INTRODUCTION

According to the design of this investigation the determination of the effect of television on pupils' interests is mainly based on the comparison of two mean difference scores, namely the experimental difference scores and the control difference scores.

The aim of the comparison of the mean group scores of the three groups of respondents (the heavy viewer group, the light viewer group and the pretelevision group) is to qualify the conclusions regarding the effect of television on the pupils' interests according to increases or decreases. For this reason reference to the results of the comparisons between the scores of the three groups is only made in cases where statistically significant differences occured in the comparison of the experimental and the control difference scores.
4.2 FIELDS IN WHICH THE INTEREST CHANGED (INCREASED)
4.2.1 Social Work (Field 3)

In the 1974/1977 as well as the 1975/1977 matched groups the mean of the experimental difference scores showed a statistically significant difference from the mean of the control difference scores ( $p<0,05$ )

## Explanation of Symbols

- $k=$ Number of respondents in each group
- $i=A$ number that can assume any value from 1 to $k$
- $A_{i}=19$ fII score of one of the members of the heavy viewers
- $B_{i}=19$ FII score of one of the members
the light views
- $C_{i}=19$ FII score of one of the members of the pretelevision group
- Difference score $D_{i}=A_{i}-C_{i}$. (where $i$ every time has the same value for
$D_{i}$, $A_{i}$ and $C_{i}$ between 1 and $k$ )
- Difference score $E_{i}=B_{i}-C_{i}$ (where $i$ every time has the same value for
$E_{i}, B_{i}$ and $C_{i}$ between 1 and $k$ )
- $X_{1}$ to $X_{k}=$ Respondents for the pre= television group
- $Y_{1}$ to $Y_{k}=$ Respondents for the heavy viewer group
- $Z_{1}$ to $Z_{k}=$ Respondents of the light viewer group
- $\bar{\delta} \quad=$ The mean of the experimental
$\begin{array}{ll}\text { difference scores } \\ \left(\bar{j}=\sum_{i=1}^{k}\right. & \left.\frac{D_{i}}{k}\right)\end{array}$
- $E \quad=\begin{aligned} & \text { The mean of the control } \\ & \text { difference scores }\end{aligned}$ difference scores $\left(\bar{E}=\sum_{i=1}^{k} \quad \frac{E_{i}}{k}\right.$ )
a) Professiona1, tecnhical and related worker
b) Administrative, executive and managerial worker
c) Clerical worker
d) Sales worker
e) Workers in agriculture, forestry, fishery and hunting
f) Mining and quarry worker
g) Transport and communication worker
h) Artisan, production worker and labourer
i) Service, sport and recreation worker.
(These categories were obtained from the Department of Statistics.) For the purpose of this investigation Categories a to $d$ were grouped together as a high occupational choice and Categories e to $i$ as a low occupational choice.* Pupils who had not decided on an occupation were classified as uncertain occupational choice.

3.1.3 Television Questionnaire

This questionnaire was also compiled by the South African Institute for Communication Research of the HSRC to obtain an indication of the television viewing habits, programme preferences, etc. of the pupils. The following questions were used.

1 How many hours per day do you usually watch television? (Mondays to Thursdays during school terms)

The design used for comparing the matched groups can schematically be represented

scores of the heavy viewers are higher than those of the light viewers while an opposite interpretation can be attached to a negative $t$ value.

The data were processed with the aid of the SAS programme system (Statistical Analysis System: Barr, et al., 1976).
3.5.2 Further comparisons

For both matchings a mean group score per field was calculated for each of the three matched groups (pretelevision group, heavy viewer group and light viewer group). In each case these scores give an indication of the interest of the particular matched group as a whole. To determine the significance of differences in. interest between the groups the mean scores were compared as follows by means of two-tailed t tests.
(a) The mean scores of the pretelevision group with those of the heavy viewer group.
(b) The mean scores of the pretelevision group with those of the light viewer group.

These further comparisons lend perspective to the findings on the effect of television on the interests of the test groups.

2 How many hours per day do you usually watch television during weekends? (Fridays to Sundays during schoo1 terms)

3 How long has your family had a television set at home?

## SAMPLE

The data in this investigation were collected in 1974, 1975 and 1977 during the comprehensive investigation conducted in provincial schools in the four provinces of the RSA. Data collecting for the comprehensive project covers a period of eight years (1974 to 1981) and in= volves pupils from Standard Three to Standard Ten. Some of the Standard. Three and Standard Six pupils included in the first survey in 1974 (before the intro= duction of television) will be followed up annually until they reach Standard Ten (follow-up pupils). For control purposes a number of pupils who have not been tested before, are also tested annually (control pupils). In this investigation into the effect of television on Standard Nine pupils' interest patterns use was made only of the data of the control pupils.

With the aid of information supplied by the four provincial education departments to the South African Institute for Communication Research in 1973 the broad sample was stratified according to sex, language medium in which the pupils are taught at school, area (urban/non-
urban situation of the schools) and province.

The test groups in this investigation were composed of respondents who had been involved in the 1974 and 1975 surveys (before the introduction of television) and in the 1977 survey (after the introduction of television). To control the novelty effect of television, data were used only of those pupils who indicated that they had had a television set at home for at least three months. The occasional viewers (i.e. viewers who had no television set at home but who watched elsewhere) were also eliminated.

The experimental group was composed of pupils who indicated in the Television Questionnaire (in 1977) that they watched television for one hour or more a day on weekdays (Mondays to Thursdays during school terms) and over weekends (Fridays to Sundays during school terms) and that they had a television set at home for at least three months. In this investigation this group of pupils is known as the heavy viewers.

Pupils who indicated in the 1977 survey that they had owned a television set for at least three months and that during the week and over weekends (during school terms) they watched television for less than one hour a day, formed the control group and are called the light viewers. To this group were added pupils who
parison (see Paragraph 3.4):

A pretelevision group
A heavy viewer group
A light viewer group

For each interest field a set of difference scores was calculated by subtracting the 19 FII score of each respondent in the pretelevision group from the 19 FII score of the corresponding matched respondent in the heavy viewer group. Later in the text this set of difference scores is referred to as the experimental difference scores. A set of difference scores between the pretelevision group and the light viewer group was calculated in the same way (control difference scores).

A mean difference score was subsequently calculated with regard to each interest field respectively for the experimental difference scores and the control difference scores. After this two-tailed tests for matched groups were used every time to study the significance of the difference between these two mean difference scores. According to this method a statistically significant difference can be regarded as an indication of the effect that television may have on the interests of the test groups. By inspection of the sign of the particular $t$ values an indication can be obtained of the direction of the effect. A positive $t$ value indi= cates that as a result of television viewing, the 19 FII

indicated that they did not have a set at home and never watched television. The pupils who were tested in 1974 and 1975 are known as the pretelevision groups.

### 3.4 MATCHING

In the child's life world there are many factors, including television, that may affect his interests (De Beer, 1980). To determine the effect of television on these interests the other factors (extraneous variables) have to be identified and controlled as far as possible. A stepwise regression analysis was done on the relevant biographical variables to determine which independent variables explained most of the variation in the interest patterns (dependent variable) of the test group. Six extraneous variables were identified in this way, namely sex, home language, the pupil's occupational choice, course followed at school, and whether the following school subjects were being taken: A third language and Geography.

To control these six extraneous variables, i.e. to make the groups as comparable as possible with regard to these variables, a process of matching was applied.

Groups of heavy viewers, light viewers and pretelevision respondents were matched for the following years:
a. 1974 with 1977
b. 1975 with 1977

The matched groups were designated as follows:
(i.) First matching (1974 with 1977)
(a) Group $C_{1}$ (the 1974 pretelevision group)
(b) Group $A_{1}$ (the 1977 heavy viewers)
(c) Group $B_{1}$ (the 1977 light viewers)
(ii) Second matching (1975 with 1977)
(a) Group $C_{2}$ (the 1975 pretelevision group)
(b) Group $A_{2}$ (the 1977 heavy viewers)
(c) Group $B_{2}$ (the 1977 light viewers)

The composition of the matched groups are shown in Tables 1 and 2.
3.5 EXPERIMENTAL DESIGN
3.5.1 Investigation into the effect of television on interest patterns

To study the effect of television two comparisons were made with regard to each interest field. A three-group design was used in each case. By a process of matching, three comparable groups were composed for each' com=
